#### Abstract

Cochlear-implant users differ significantly from their normal-hearing peers when it comes to perception of music. Several studies have shown that structural features - such as rhythm, timbre, and pitch - are transmitted less accurately through an implant. However, we cannot predict personal enjoyment of music solely as a function of accuracy of perception. But can music be pleasant with a cochlear implant at all? Our aim here was to gather information of both music enjoyment and listening habits before the onset of hearing loss and post-operation from a large, representative sample of Danish recipients. A hundred and sixty three adult cochlear-implant users ( 101 females, 62 males) completed a survey containing questions about musical background, listening habits, and music enjoyment. The results indicate a wide range of success with music, but in general, the results show that the CI users enjoy music less post-implantation than prior to their hearing loss. Nevertheless, a large majority of CI listeners either prefer music over not hearing music at all or find music as pleasant as they recall it before their hearing loss, or more so.

## BACKGROUND

A cochlear implant (CI) is a neural prosthesis that restores hearing sensation in deaf individuals. The clinical impact of the evolution of CIs has been nothing less than extraordinary, and over 250,000 individuals worldwide use the device (Peters et al. 2010). While the majority of adult CI users achieve good speech perception in quiet, auditory processing in general and music perception in particular are hampered. This is supported by several studies showing that discrimination of pitch, melody, timbre, and emotional prosody is significantly poorer in CI-users than in normally-hearing controls (Gfeller et al., 2007; Cooper et al., 2008; Petersen et al., 2012).

[^0]Nevertheless, some users seem to overcome the technical limitations of the implant and enjoy music immensely (Gfeller et al., 2000). Because music is an important part of our everyday life with great emotional and social aspects, it is reasonable to evaluate the extent of music listening in CI users and identify possible factors that impacts music appreciation. With this study, we aimed to gather information about music listening habits and music appreciation before the onset of hearing loss and after receiving an implant from a large, representative sample of Danish CI users. Furthermore, we aimed to correlate this information with self-reported measures of quality of life (QOL).

## PARTICIPANTS

All adult CI recipients ( $\geq 18$ ) implanted at the ENT department, Aarhus University Hospital, between January 1st 2000 and December 31st 2010, were invited to take part in the study. Of the 250 patients, 163 responded ( 101 female; $M_{\text {age }}=56.4 \mathrm{y} ; S D$ $=15.7$; age range: 18 to $86 \mathrm{y} ; 65 \%$ response rate). A hundred and seventeen respondents filled out the questionnaire online, while 46 requested the printed version. The implant experience ranged from 0.4 years to 11.2 years ( $M=4.3 \mathrm{y}, S D$ $=2.65$ ). One hundred and thirty seven ( $84 \%$ ) participants used an implant from Cochlear ${ }^{\circledR}$ and $26(16 \%)$ participants used an implant from Advanced Bionics ${ }^{\circledR}$. The demographic data of the respondents are listed in Table 1.

| Respondents <br> (M/F) | Mean age (years) | Duration of profound deafness | Mean CI experience |
| :---: | :---: | :---: | :---: |
| $\begin{gathered} 163 \\ (62 / 101) \end{gathered}$ | $\begin{gathered} 56.44 \\ ( \pm 15.7 \text {; } \\ 18-86) \\ \hline \end{gathered}$ | $\begin{gathered} 34.5 \\ ( \pm 18.2 ; \\ 75.3-1.1) \end{gathered}$ | $\begin{gathered} 4.3 \\ ( \pm 2.6 \\ 0.4-11.2) \end{gathered}$ |
| Unilateral users (R/L) | Bilateral users | Users of hearing aid on nonimplanted ear | Able to speak on the phone |
| $\begin{gathered} 147 \\ (108 / 39) \end{gathered}$ | 16 | 73 | 106 |

Table 1: Demographic data for the 163 respondents in the study.

## METHOD

The questionnaire used in the study was a modified, Danish version of the IOWA Musical Background Questionnaire (Gfeller et al., 2000). The 21 questions in the survey included multiple-choice, Likert rating scales, visual analog scales, and openended questions concerning musical background, listening habits, the quality of musical sound heard through the implant, and music enjoyment prior to hearing loss and after cochlear implantation. In addition, respondents were required to fill out two questionnaires concerning their quality of life (QOL) post-implantation: the

Short Form 36 (SF 36, Ware and Sherbourne, 1992) and the Glasgow Benefit Inventory (GBI, Robinson et al., 1996). Here, the QOL data were used for correlational analyses.

## RESULTS

## Musical background

$23.9 \%$ of the participants had received singing and/or instrument lessons (in primary school: $M=3.6 \mathrm{y}$; in high school: $M=1.5 \mathrm{y}$ ). $12.9 \%$ had been a member of a band, choir, or an orchestra. Table 2 sums up the respondents' self-assessed knowledge and experience with music. In total, $77 \%$ were involved in music to a lesser or larger extent. This is in agreement with Gfeller et al. (2000) and considered representative of the general population.

| Category | Percentage |
| :--- | ---: |
| No formal training and only limited knowledge about music | $23 \%$ |
| No formal training or knowledge about music, but informal <br> listening experience | $56 \%$ |
| Autodidact musician | $3 \%$ |
| Some musical training and have basic knowledge of <br> musical terms | $12 \%$ |
| Several years of musical training, knowledge about music, <br> and involvement in music groups | $4 \%$ |

Table 2: Self-assessment of musical experience.

## Music listening habits

The participants indicated on a four-point Likert-scale to what degree they would consider themselves as a person who often chose to listen to music (i) before the hearing loss and (ii) after receiving their implant (from 1 point $=$ strongly disagree to 4 point = strongly agree). Furthermore, they indicated how often they chose to listen to music before their hearing loss and after getting accustomed to their implant, respectively (from 1 point $=0-2$ hours per week to 4 points $=9$ hours or more per week). Summed and averaged, the scores were used as mean composite scores for pre- and post-music listening habits. The mean composite score for music listening habits prior to hearing loss was $4.96(S D=1.86)$. The mean composite score for listening habits post-implantation was lower, at $4.23(S D=1.76)$. A paired $t$-test showed that the difference was significant $(t=3.6, p=0.000)$.

## Quality of musical sound

Figure 1 shows the mean values for the seven adjective descriptors of music through the implant. The average quality rating across all descriptors was 56.1, indicating a positive trend.

Fig. 1: Mean scores for adjective descriptors of music through the implant.

## Music enjoyment

Figure 2 shows the respondents' evaluation of how their music enjoyment has changed after receiving their implant. The two rightmost categories ( $37 \%$; 44\%) indicate a range of music enjoyment. The left category (19\%) indicates no music enjoyment.

## Correlations

The ability to talk on the phone showed a weak positive correlation with both music listening habits ( $r=0.233, p=0.003$ ), quality of musical sound ( $r=0.361, p=$ 0.000 ), and enjoyment ( $r=0.138, p=0.013$ ). Furthermore, age was negatively correlated with music listening habits ( $r=-0.264, p=0.000$ ), quality of musical sound ( $r=-0.245, p=0.001$ ), and enjoyment ( $r=-0.389, p=0.000$ ). No other demographic factors showed any significant correlation with any measures of music listening. The composite scores of the GBI questionnaire showed a significant correlation with music listening habits ( $r=0.329, p=0.000$ ), quality of musical
sound ( $r=0.408, p=0.000$ ), and enjoyment ( $r=0.326, p=0.000$ ). Furthermore, the social functioning subscale of the SF 36 questionnaire data showed correlations of similar strength with the three music listening measurements.

## DISCUSSION

In line with findings by Gfeller et al. (2000), this study shows that in general adult CI users enjoy music less post-implantation than prior to hearing loss. In addition, the findings show a wide range of success with music. Interestingly, a large majority of CI listeners seem to listen to and enjoy music ranging from modest satisfaction to great enthusiasm, despite the technical disadvantages of the CI's music presentation. Furthermore, on average, the respondents describe their appreciation of different aspects of music slightly more positively than those in the Gfeller et al. (2000) study. This difference may suggest a benefit from the technical improvements achieved in the last decade. Interestingly, our findings indicate that solely the ability to talk on the phone is associated with success in all aspects of music listening. Previous studies found that both use of contralateral hearing aid and duration of
deafness were predictive for music perception with a CI (Looi et al., 2008). However, no such correlations were found in the present study. In accordance with Lassaletta et al. (2007) our findings suggest an association between QOL and success in music listening. Although the causes for this association may be manifold, this suggests that music exposure or training could be beneficial not only for CI users' perception of music, but also for their QOL.

## ACKNOWLEDGMENTS

This study was supported by the Augustinus Foundation, Ejner Danielsens Foundation, and Danaflex A/S.
